# Haystacks

- Many environmental sensors deployed in last decade
- Each sensor collects environmental observations
  - Sometimes many per second
- Each observation has:
  - a time;
  - a location;
  - observed variables
- Observational data stored in many formats, many datasets

# Needles

- Scientists at CMOP name “finding data relevant to their research” as one of their biggest problems<sup>2</sup>
- Example query:
  - “Any observations near the Astoria bridge in June 2009”

# Problem: Finding Haystacks that Contain Needles

- Problem: Which datasets contain relevant data?
  - Many scientific datasets have no metadata
  - Many scientific datasets not indexed
- Potential solution: extract simple dataset bounds, perform Boolean search
  - But: many false positives

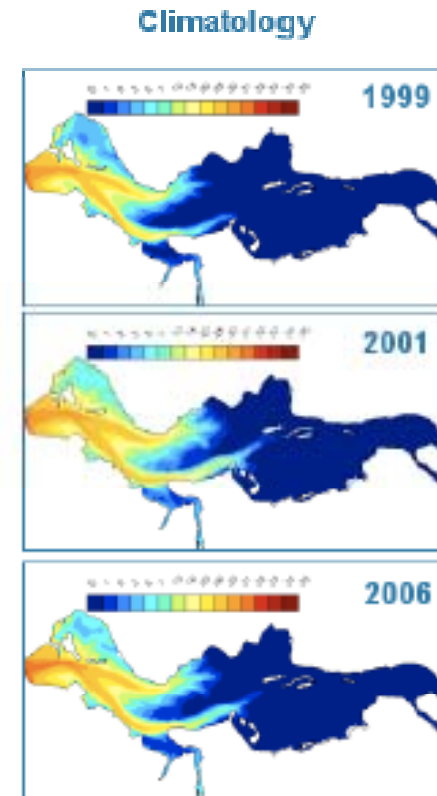

Our Approach:

1. Create hierarchical metadata to represent dataset contents
2. Query over metadata
3. Rank query results

# Current Approaches / Related Work (1)

- Search via data visualization
  - Given a specific dataset and data ranges, display the (large amount of) data
  - Most common approach so far
- But: How does the scientist identify relevant datasets and ranges for visualization?

Example of visualization approach  
[Howe et al. 2009]

## Current Approaches / Related Work (2)

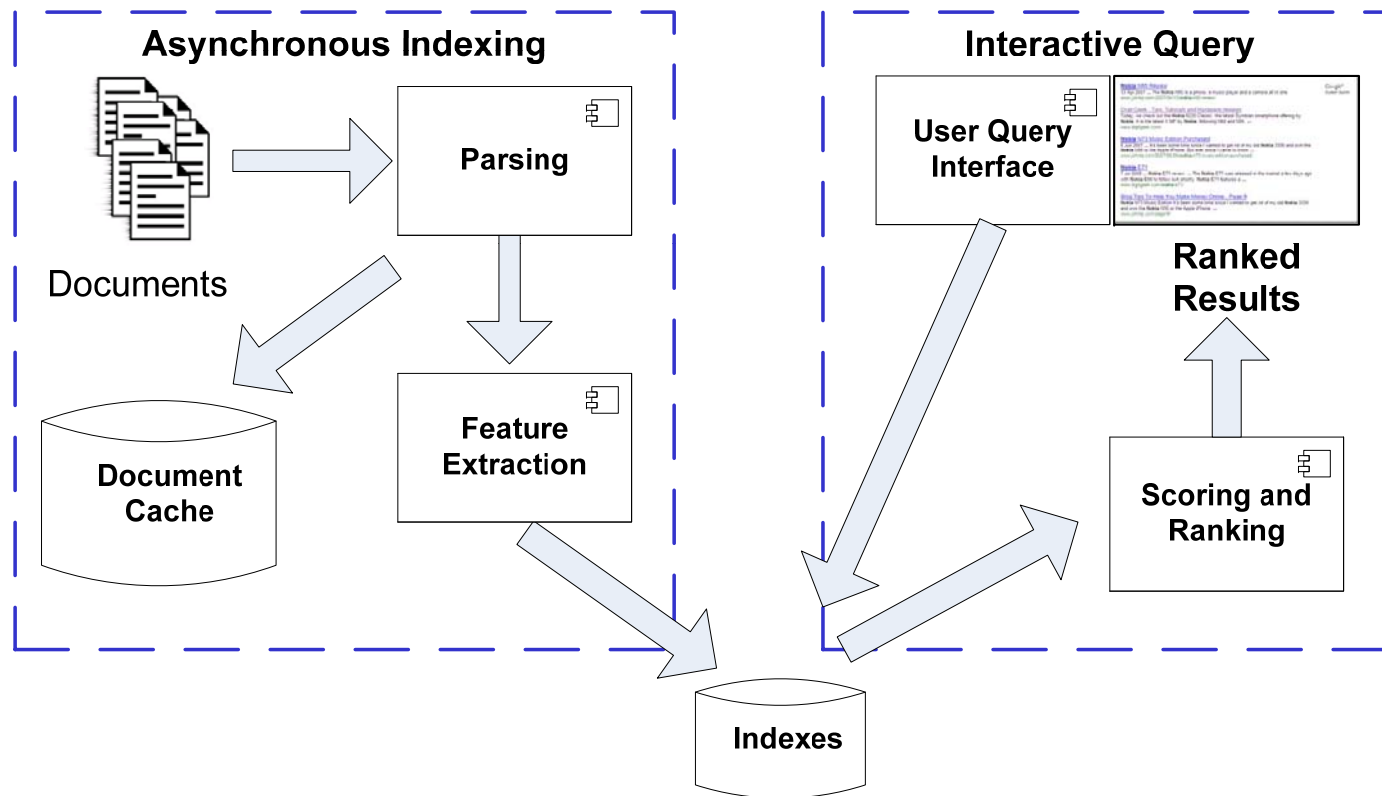

- Metadata search
  - Text search of manually-added metadata
    - E.g. “Salinity, Columbia River”
  - Boolean search on time and location (rare)
    - Some advanced geoportals provide spatial tests:
      - E.g. dataset *intersects* or *completely contains* query area
- But:
  - Boolean search: No matches: no results (1)
  - Search results not ranked (2)

There were 3840 results returned

## Current Approaches / Related Work (3)

- In Information Retrieval:
  - Ranked retrieval of unstructured text documents

- But text retrieval techniques not suited to searching the contents of scientific datasets

# Research Questions

? How can we rank datasets?

? Does the ranking approach resonate with users?

? What features should we extract from scientific datasets ...

? ... that would allow us to perform real-time search over the extracted features?

Spatial and temporal features selected for initial case study

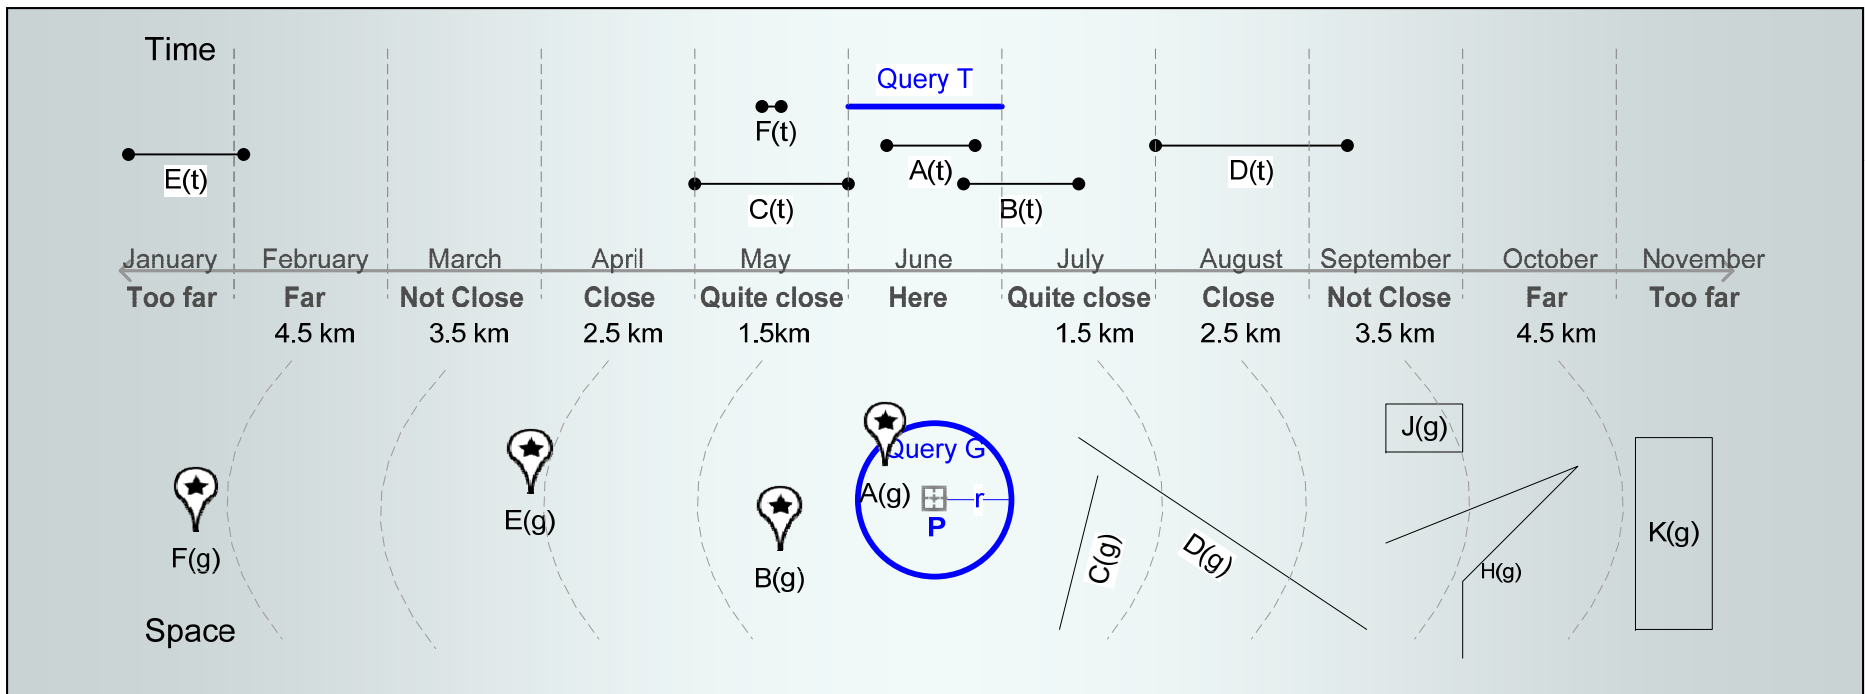

## Research Contributions

- ❖ Proposed a mental model of how scientists perceive dataset similarity for space and time characteristics
  - ❖ Tested mental model in a user study
- ❖ Developed hierarchical metadata to represent dataset contents
  - ❖ Extracting features at multiple granularities
- ❖ Developed a prototype query engine with real-time response

# Space-Time Ranking: Mental Model

- Example Query: “Observations within  $\frac{1}{2}$  km of point ‘P’, in June 2009”
- Each dataset A, B, ... represented by its time extent  $A(t)$ ,  $B(t)$ , ... and its geospatial extent  $A(g)$ ,  $B(g)$ , ...

- Relative “weight” of space to time given by the “range” of each query term

## Scoring Datasets (2)

- Given a time query  $T$ , calculate a time-relevance score  $d_{TS}$  for dataset  $d$

- Calculated scores can range from 100 for an exact match to query terms to negative numbers for datasets “too far” from query

# Ranking Datasets

- Overall relevance score  $d_{score}$  for each dataset  $d$  is composed using the geospatial and temporal scores:

$$d_{score} = (d_{Gs} + d_{Ts}) / 2$$

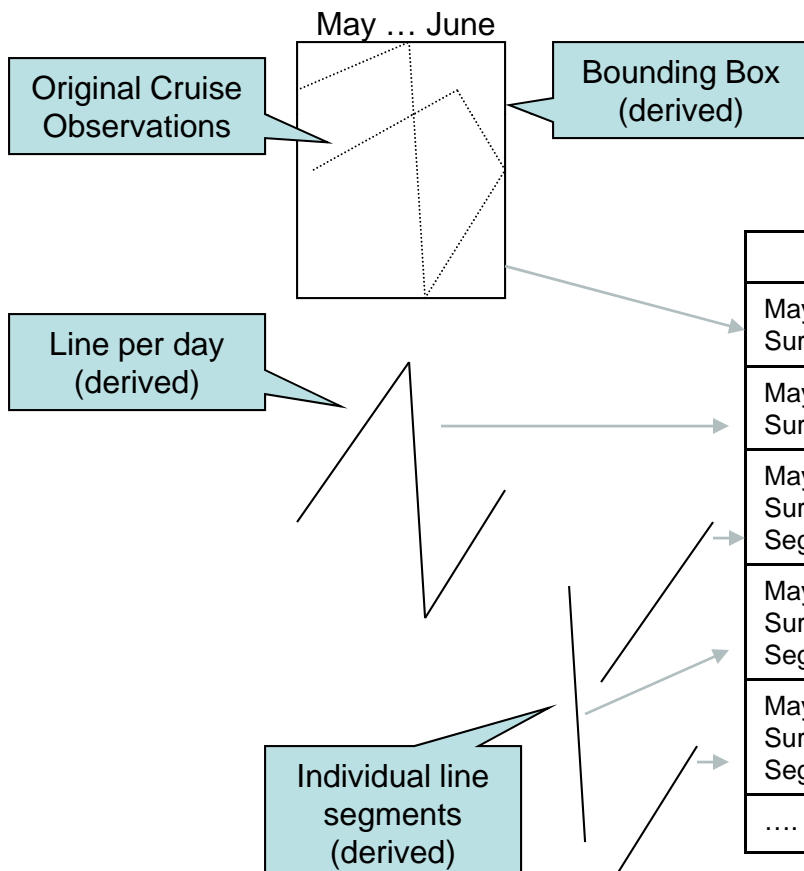

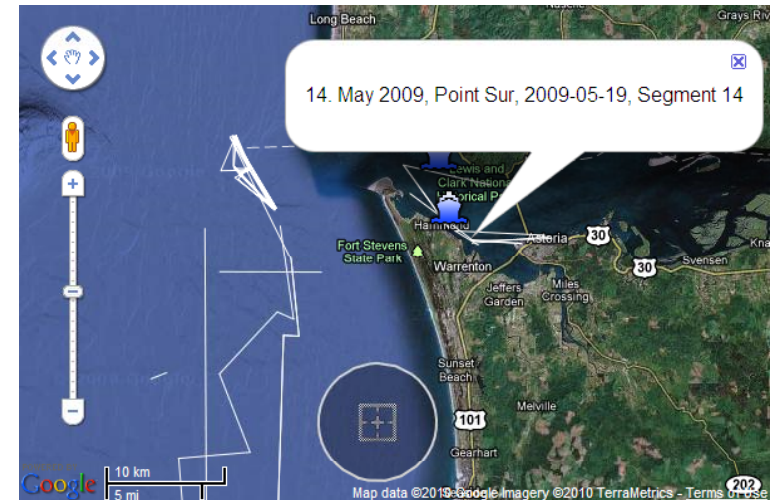

- Datasets are then ranked by decreasing relevance score.

# Ranking

- Tested relevance ranking with a user study:
  - Proposed relevance measure appears to approximate user expectations
  - Relevance-measure “tuning” may further improve match with user expectations
    - “Closest edge” has more weight than “centroid” or “farthest edge”
- Scoring/ranking approach assumes appropriate **indexes** over which to operate
  - Query terms should relate to indexed features
  - Features represent **metadata** used to describe dataset content

# Creating Metadata: Extracting Features for Space and Time

- Transform observations into features
  - Extract at multiple granularities
  - Model features as “footprints”
  - E.g.: 1 million observations over 3 weeks

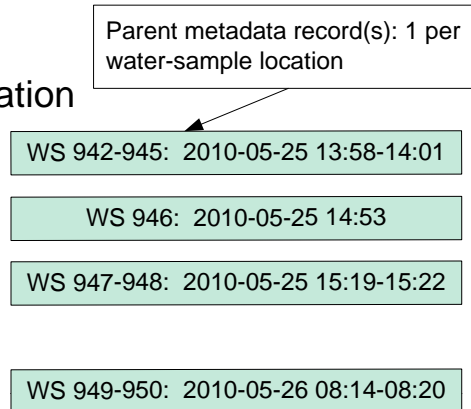

DNH Metadata Table

	<b>Geometry</b>	<b>Mintime</b>	<b>Maxtime</b>	<b>Parent</b>

....				

# Metadata: Adaptive Hierarchy

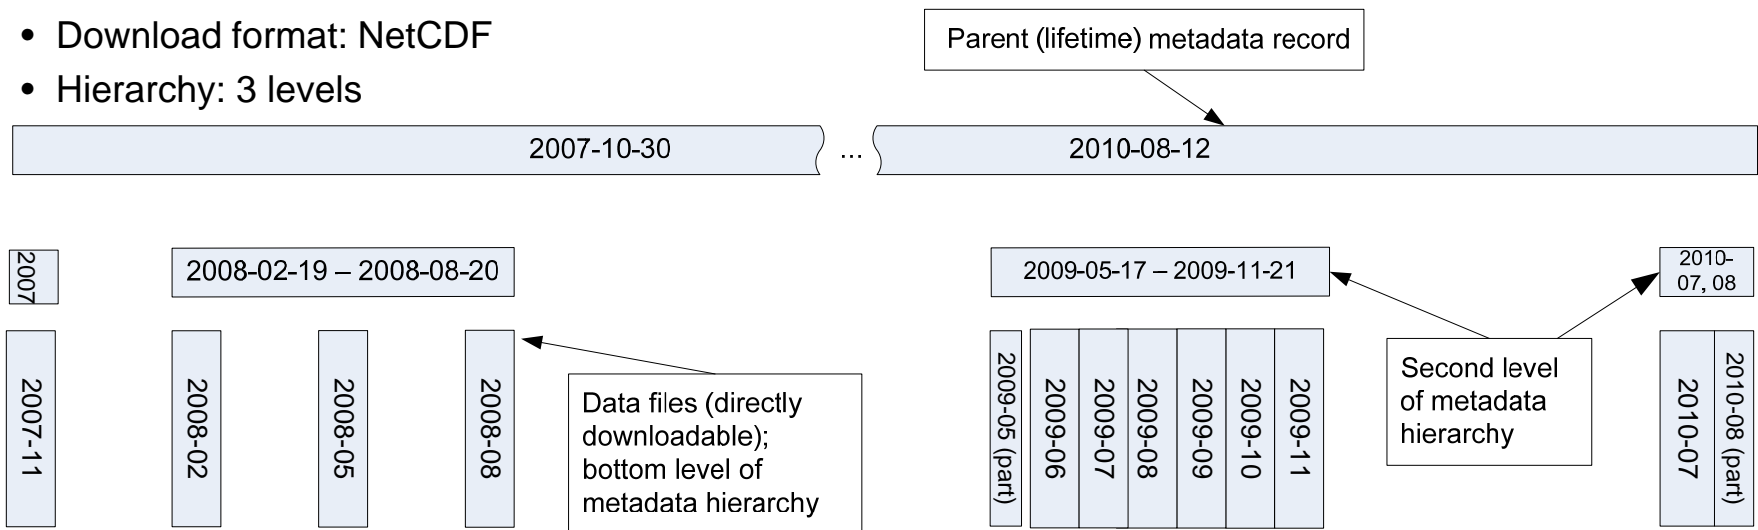

## Water samples:

- 1-3 observations per location
- Time: minutes
- Download format: CSV
- Hierarchy: 1 level

## Fixed Stations:

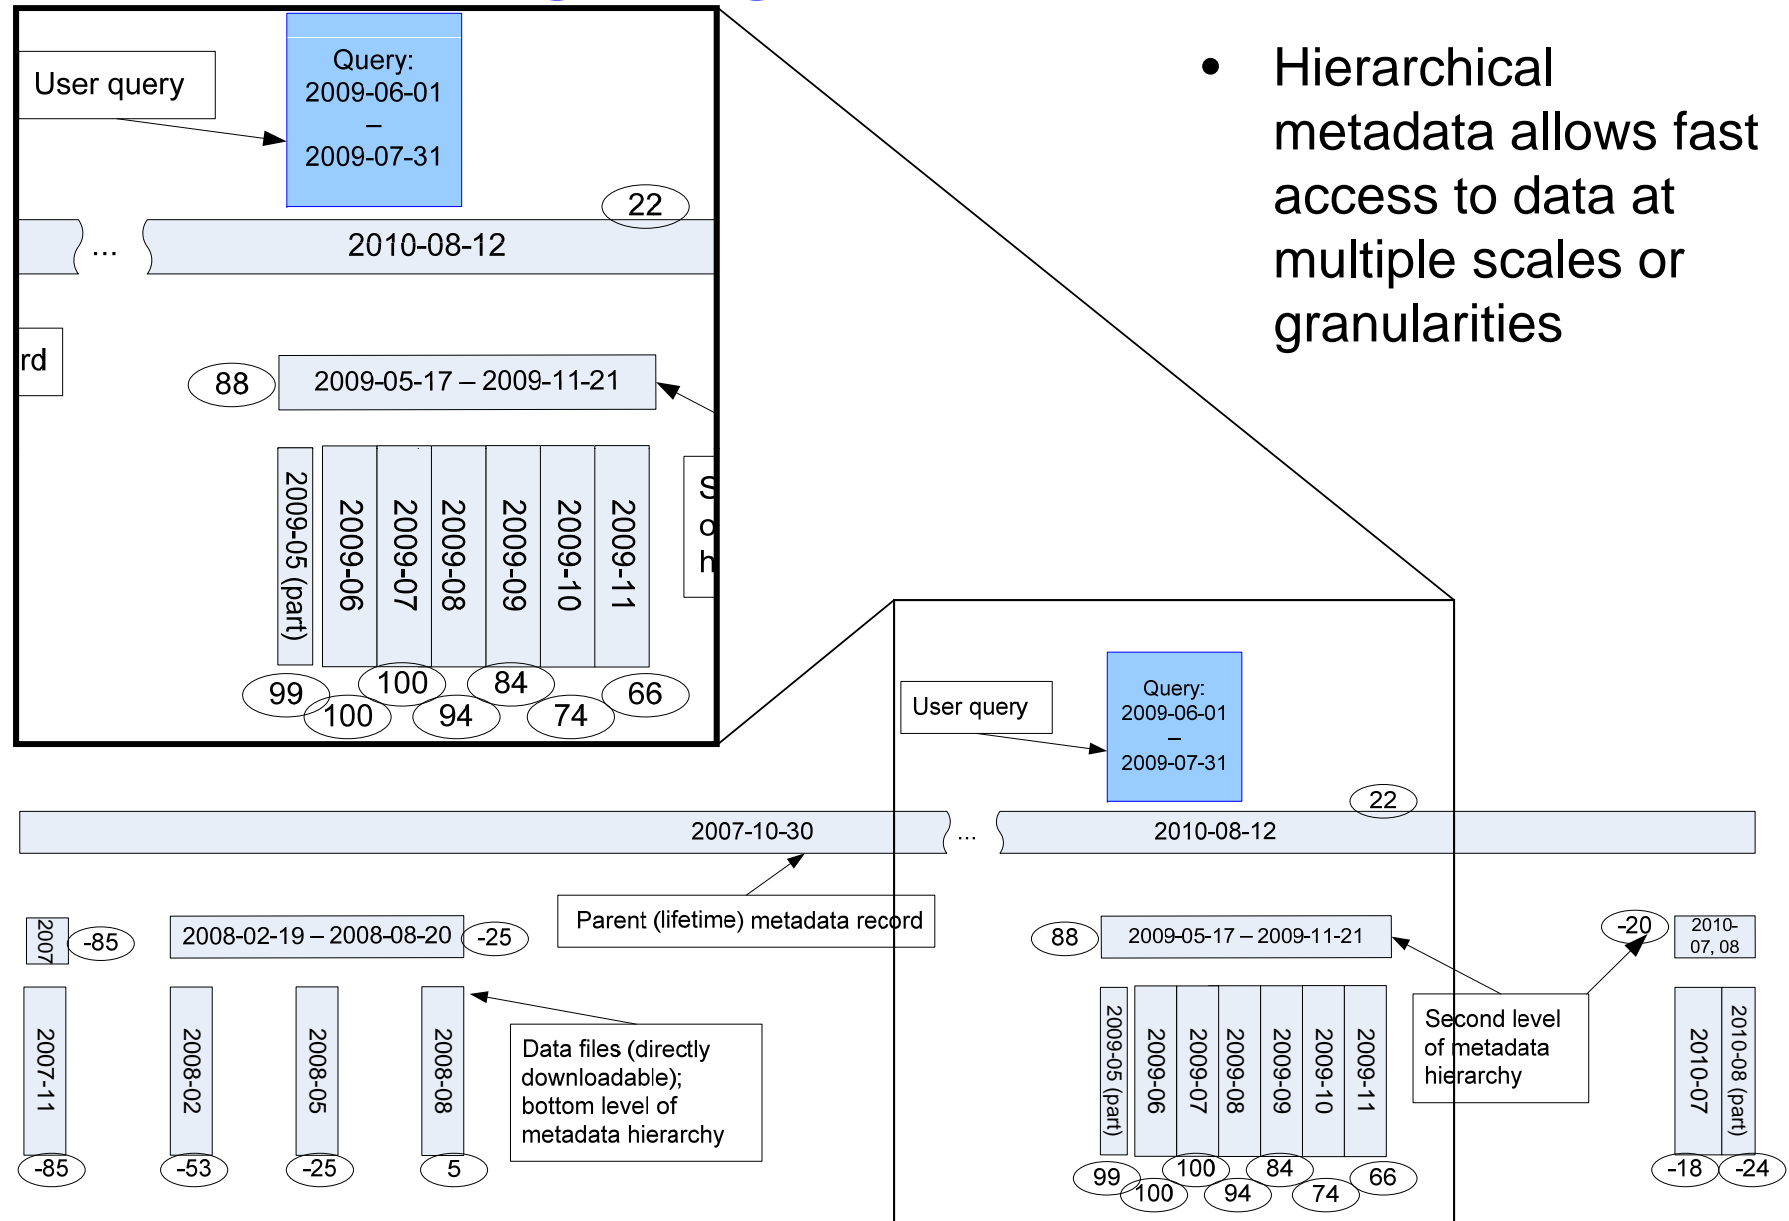

- 1 location
- Time: months-decades
- Observations: millions
- Download format: NetCDF
- Hierarchy: 3 levels

- Multiple depths of hierarchy are accommodated simultaneously
- Curation decision(s) made once per kind of data/dataset

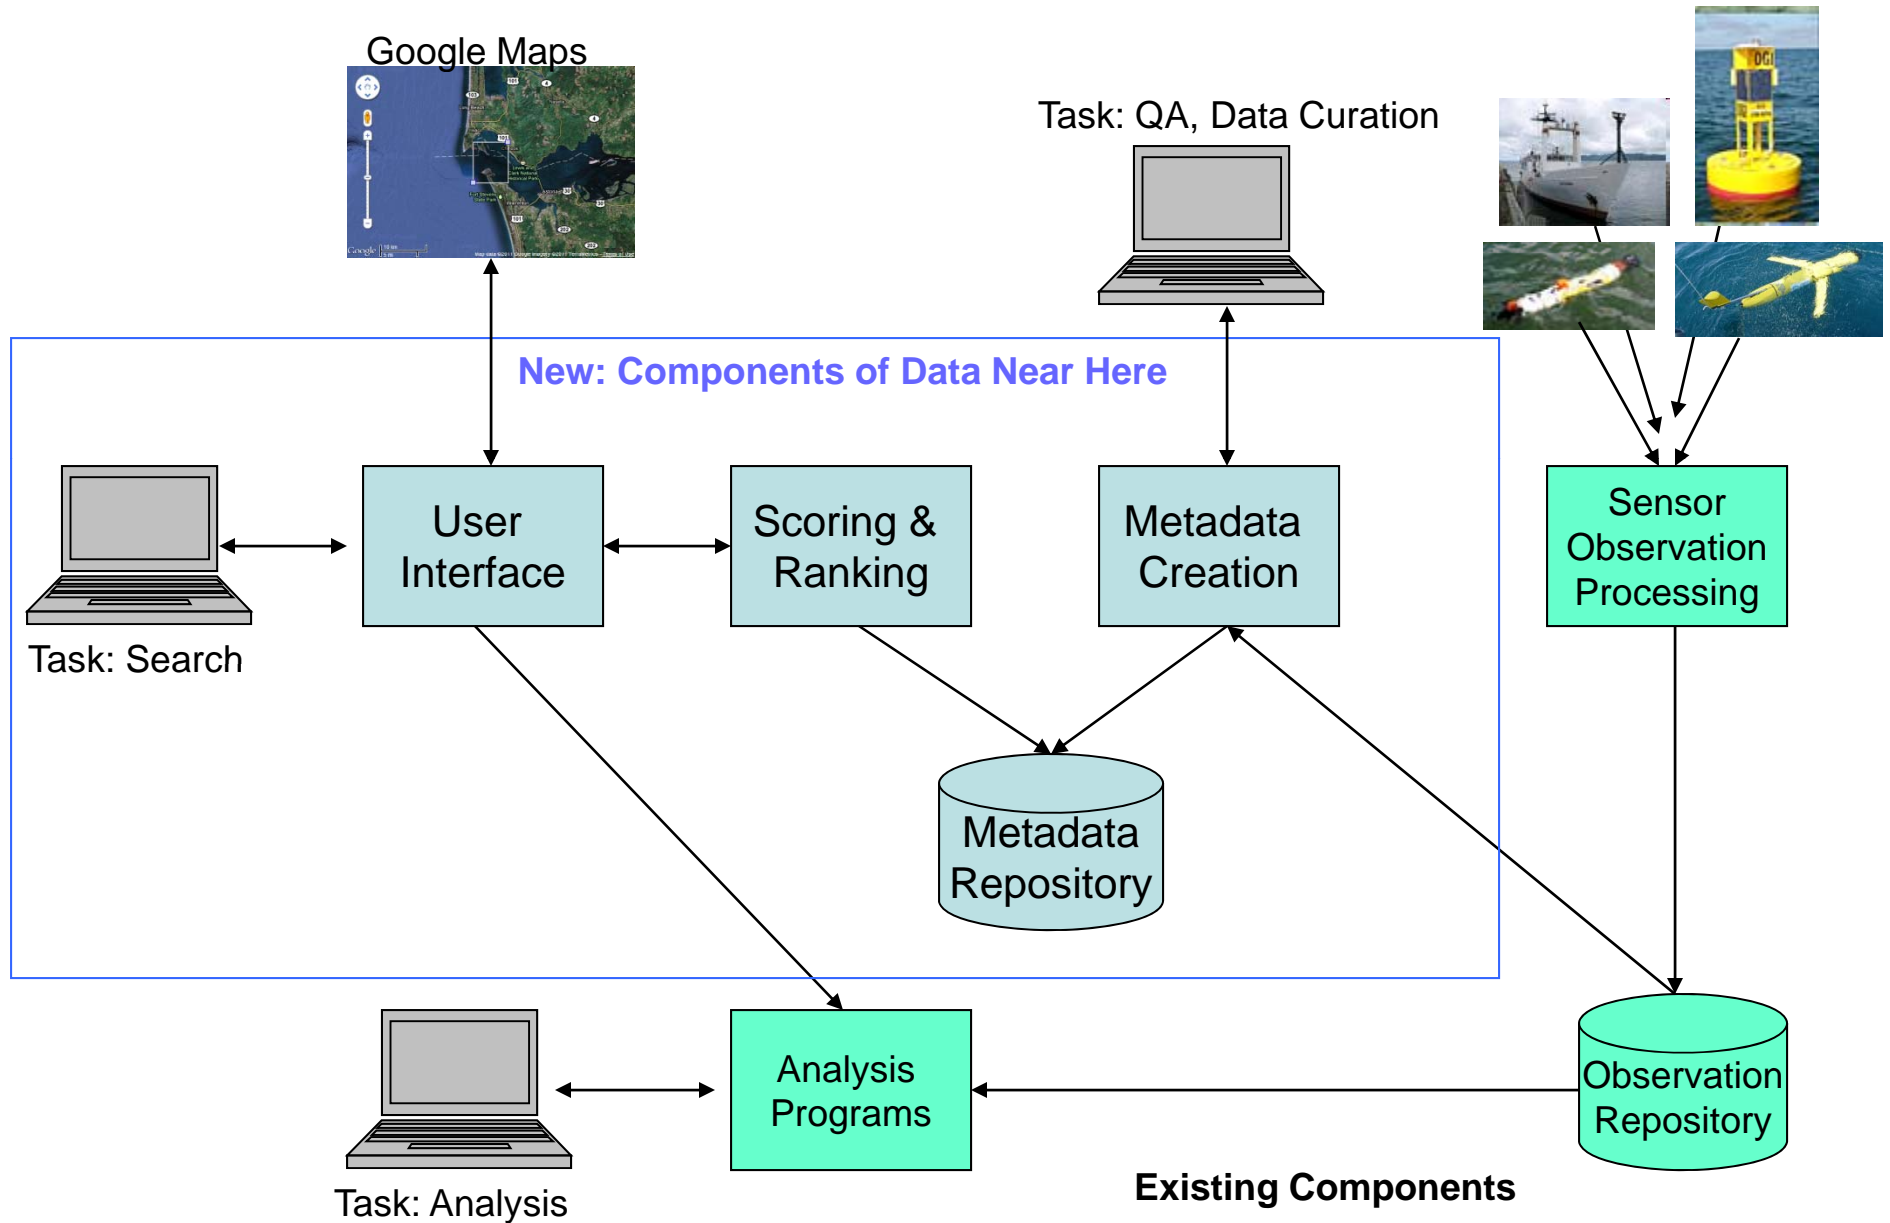

# Scoring using Hierarchical Metadata

- Hierarchical metadata allows fast access to data at multiple scales or granularities

# System Components

# The Prototype: “Data Near Here”

**Data Near Here V0.3**

Please enter the following parameters:

Categories: ALL (selected), AUV, Cast-Binned

Lat Long [dec. deg]: 46.23, -123.88      Radius [m]: 4000

Start date: 2009-06-01      End date: 2009-07-01

Display parameters:

Min. Obs. Count: 1

# to Display (0=all): 100

- ✓ Extracted metadata for ¼ billion observations → 15,500 metadata records
- ✓ Developed an interactive user interface: [Demo](#)
  - ✓ Accepts spatial and temporal query terms
  - ✓ Ranks datasets by decreasing score
  - ✓ Provides real-time response

# Conclusion

Our research demonstrates methods for:

- ✓ Ranking scientific datasets in response to a spatio-temporal query
- ✓ Automatically extracting hierarchical metadata from scientific datasets ...
- ✓ ... and searching over the extracted features
- ✓ Providing real-time response times for queries over  $\frac{1}{4}$  billion observations in a multi-terabyte data repository

# Current Research

- ⌚ Evaluation of metadata scalability
- ⌚ Add elevation / depth: 4-dimensional search
  - ⌚ 2+1+1 versus 3+1
- ⌚ Add additional search criteria:
  - ⌚ Observational variables
  - ⌚ ... “with oxygen below 3 mg/liter, where Myrionecta Rubra are present”
